### **Executive Summary**

This report describes how the knowledge base system (KBS) database is built and populated to represent, store, and manage all the experimental and research data generated in WP2, WP3, and WP4. First, the KBS database design process identified all possible entities relevant to experiments and analysis performed in the GeoSmart project and extracted properties of and relationships between these entities. Next, the entities, properties, and relationships are converted to database tables, attributes, and relational tables. State-of-the-art open-source database technologies such as Postgres [1] and Parse Platform [2] are used to develop the KBS database. Following the execution of the development process, data and experimental results received from project partners are populated into the database. The report also describes the web-based data management panel, class documentation, and application programming interface (API). In Task 5.7, the knowledge-based system (KBS) and decision support system (DSS) with graphical user interfaces (GUI) will use this KBS database as a knowledge base.

## **Objectives Met**

Develop the GeoSmart system simulator suite which combines flow assurance simulator, knowledge based engineering, and decision support systems, to provide robust options for future design capability across diverse European geothermal sites, investment decision making and policy analysis.

### **1. INTRODUCTION**

In task 5.5, a relational database is designed, developed, and deployed on the web. The database is populated with experimental and research data generated in WP2, WP3, and WP4.

Concrete details about the database components and tables relevant for representing data and establishing relationships between data elements are extracted by analysing the following reports from WP2, WP3, and WP4:

- D2.1 Correct material choices documented for Demosites (submitted)
- D2.2 Energy storage system design schematics (submitted)
- D2.3 Heat exchanger design trial report (submitted)
- D2.5 Insheim system designed (submitted)
- D2.6 Zorlu system designed (submitted)
- D2.7 Final material choices documented for demo sites (submitted)
- D3.1 ORC Model ready for off-design performance estimation with constraints (submitted)
- D3.2 Control system software built (submitted)
- D3.3 Groundwater system installed and tested (submitted)
- D3.7 ORC Model ready for off-design performance estimation with constraints 2 (submitted)
- D4.1 Modelling of silica scaling potential (submitted)
- D4.2 Report on the formulation of inhibitor against silica scaling (submitted)
- D4.3 Report on the preliminary design of HX, including materials compatibility investigation (submitted)
- D4.4 Report on optimisation of the design of HX (submitted)
- D4.5 Report on design and building of retention tank (submitted)
- D4.6 Heat-exchanger produced (submitted)
- D4.7 Retention Tank Produced (submitted)

These reports described the design specifications of three types of thermal energy storage (TES) systems: a scaling reduction system comprising a scaling heat exchanger, a scaling reactor and retention tank, and an adiabatic cooling system.

The experimental results' design specifications, parameters, and relationships between thermal energy storage (TES) systems, the scaling reduction system, and the adiabatic cooling system have been identified, analysed, and extracted for designing the database tables and properties. Also, primary cost data and life cycle assessment (LCA) models are identified, analysed, and extracted to create the database for GeoSmart components. Finally, the database is populated with data published in the reports through a data management tool developed as part of the database design. The rest of this report is structured as follows:

- Section 2 overviews the database design process and its outcome as the entity relationship diagram.
- Section 3 describes the database development process using the Postgres [1] and Parse Server [2] technologies.
- Section 4 shows the database population techniques using data management tools and RESTful application programming interfaces (APIs) [3].
- Section 5 provides the overall conclusions.

Version: 1.0

Date: 25 March 2024

## 2. KBS DATABASE DESIGN

### 2.1 Overview

The Knowledge Base System (KBS) database is a relational database designed to extract all the entities and their properties and relations. The extracted entities are:

- Thermal Energy Storage (TES) Systems
  - $\circ$  PCM (brine) storage system
  - $\circ$  Steam accumulator
  - Water thermocline
- Separator

•

- New IP separator
- Scaling reduction system
  - Scaling Heat Exchanger
  - Scaling reactor
  - Retention tank
- Adiabatic Cooling System
- Basic cost data and parameters
- Life Cycle Inventory (LCI) data and parameters

## 2.2 Entity Relationship Diagram

The entity-relationship (ER) diagram is a high-level visual representation of a database system. It is often an initial step to model a particular database. ER diagrams help to define entities, attributes, and relationships. ER diagrams have been modelled for each extracted entity mentioned in section 2.1.

An example of an ER diagram of the PCM storage system table is depicted in the Figure 0.1. The PCM storage system table represents, stores, and manages data and metadata about the PCM storage system used in the GeoSmart project. The PCM storage system table has many properties reflected in the ER diagram used in the GeoSmart project. ER diagrams of other entities or tables are provided in Appendix A.

#### Version: 1.0

Figure 0.1 ER diagram of PCM storage system entity

### 3. KBS DATABASE DEVELOPMENT

The relational database implementation is completed using Postgres, an open-source database suitable for managing a large volume of data. It also uses Parse Server, which enables the design and development of database tables in Postgres. While developing database tables on Parse Server, each table is treated as a class and the table's attributes as the class's attributes. The codes to create the tables in Postgres via the Parse Server API were written in Ruby. A database management system has also been developed to manage data from user-friendly graphical interfaces.

Figure 3.1 shows a concrete example of the class, which corresponds to the relational database table PCM storage system. The figure depicts that the PCM storage system is a class that inherits the attributes from the

Version: 1.0

#### **Date:** 25 March 2024

class Parse Object. This figure provides an example to show how to instantiate the PCM storage system class using Ruby. Another example, PCM\_storage\_system.save, illustrates how to save the already created instance of the PCM storage system.

Figure 0.1 also demonstrates that the class definition of a PCM storage system consists of various attributes, such as the amount of tap water used per cleaning, annual thermal energy stored, amount of PCM material, average amount of cleaning material, input temperature of brine, and outlet temperature of brine. A list of classes and their definitions is provided in Appendix B.

## 4. KBS DATABASE POPULATION

### 4.1 Overview

Data about thermal energy storage (TES) systems, scaling reduction systems, New IP separator, and adiabatic cooling systems from the experimental results into the database was populated in two ways: automatic and manual. For the automatic data population, easy-to-use RESTful Application Programming Interfaces (APIs) were developed. For adding data manually, a data management tool with an intuitive user interface was built.

### 4.2 RESTful APIs

A group of RESTful Application Programming Interfaces (APIs) or RESTful web services is developed to programmatically upload data to the relational database. These facilitate importing data from a comma-separated value (CSV), tab-separated value (TSV), or excel file.

The GET command is implemented to read information about the schema of the relational database. A database schema consists of all the tables and relationships between them. As shown in Figure 0.1, Figure 0.2, and Figure 0.3, the GET and POST commands are implemented for each table.

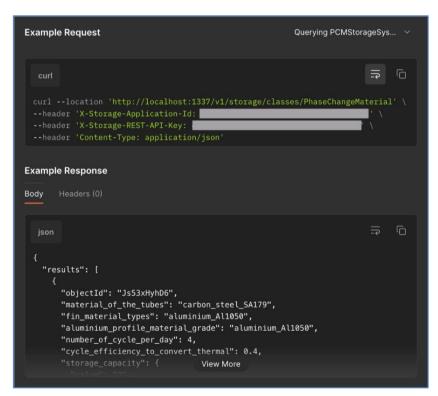

Figure 0.3 A sample POST request to create a PCM storage system in the GeoSmart relational database.

### 4.3 Data management tool

A web-based data management tool is created to allow users to populate information about one entity at a time into the relational database. The tool supports the read, update and delete operations along with the data population. As shown in Figure 0.4, the user interface of the tool is designed using a dashboard layout for ease

Version: 1.0

## **5. CONCLUSIONS**

The relational database design, development, and population are based on the data published in WP2, WP3, and WP4 project deliverables. Clarifications about the data are sought from the partners as often as needed during the database design and population tasks. The database design has been updated with the updated data available from the partners. The crucial web links related to this deliverable are provided below:

- The GeoSmart Database Management Tool: http://138.68.144.219:3000/login (for consortium members to manage data).
- The RESTful APIs of the database: <u>RESTful APIs</u>. The complete list of RESTful APIs is provided in Appendix C
